Semester 2

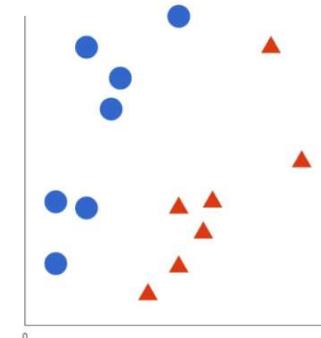

Support Vector Machines

- **Support Vector Machine** is a **Supervised Machine Learning Algorithm**
- SVM can be used for both **Classification** and **Regression** Tasks. But more prefers for Classification Tasks
- Support Vector Machines may be used for both **linear separable** and **non-linear separable** data
- The objective of SVM is to find a **hyperplane** that **maximally separates** the different classes in the training data

Types of SVMs

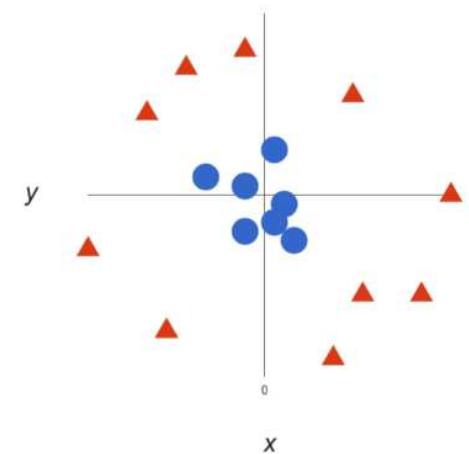

Simple (Linear) SVM

- A linear SVM refers to the SVM type used for classifying linearly separable data.
- This implies that when a dataset can be segregated into categories or classes with the help of a single straight line

Kernel (Non-Linear) SVMs

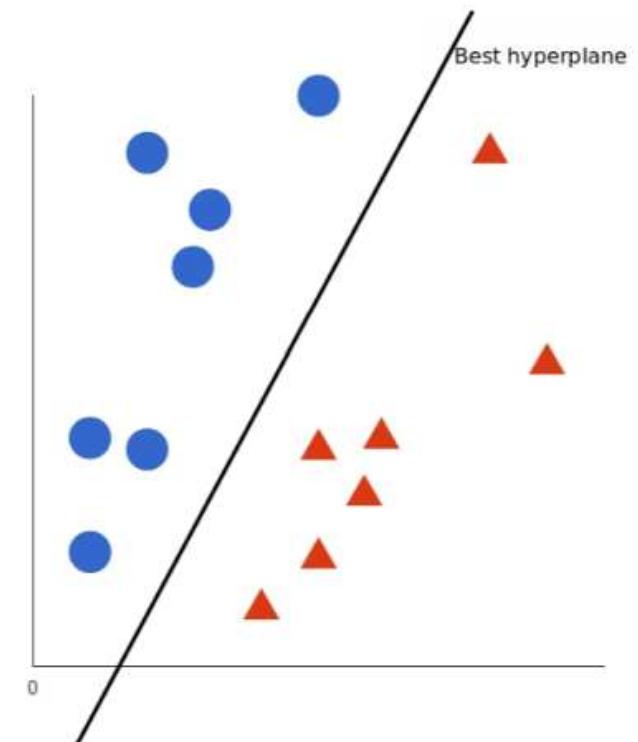

- Non-linear data that cannot be segregated into distinct categories with the help of a straight line is classified using a kernel or non-linear SVM

Hyperplane

- Hyperplane is plane that classifies the data into multiple classes
- Hyperplane may be 2D, 3D... (n-1) Dimensional etc depending on the number of dimensions of the data

No of Features (No of Dimensions)	Feature Representation	Hyperplane
1	(x_1)	Point (Zero Dimension)
2	(x_1, x_2)	Line (1 Dimensional)
3	(x_1, x_2, x_3)	2D Plane (2 Dimensional)
n	$(x_1, x_2, x_3, \dots, x_n)$	(n-1) Dimensional

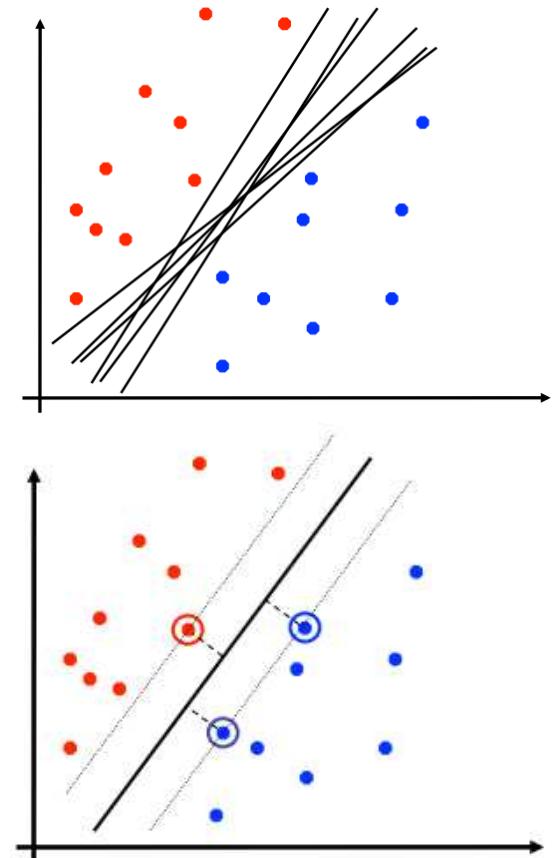

Margin & Support Vectors

Margin: The distance between the Hyperplane and the closest data points from each class

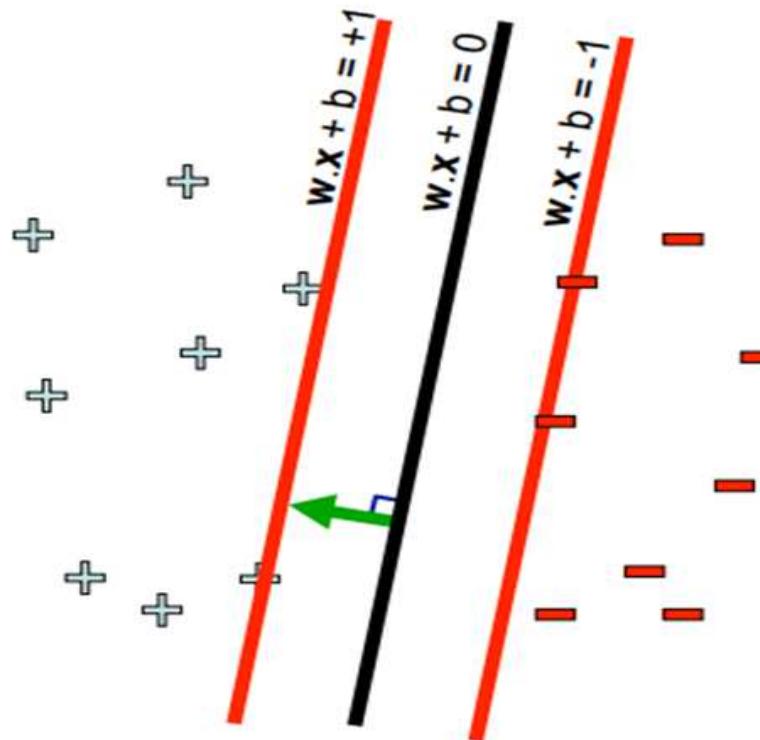

Optimal Separating Hyperplane: The hyperplane with the maximum margin is called the Optimal Separating Hyperplane

Support Vectors: The data points that lies closest to the optimal separating hyperplane are called Support Vectors

SVM Chooses the linear separator with the **largest margin**

Mathematical Formulation of SVM

For every data point (x_t, y_t) , enforce the constraint

$$\text{for } y_t = +1, \quad w \cdot x_t + b \geq 1$$

$$\text{and for } y_t = -1, \quad w \cdot x_t + b \leq -1$$

Equivalently, we want to satisfy all of the linear constraints

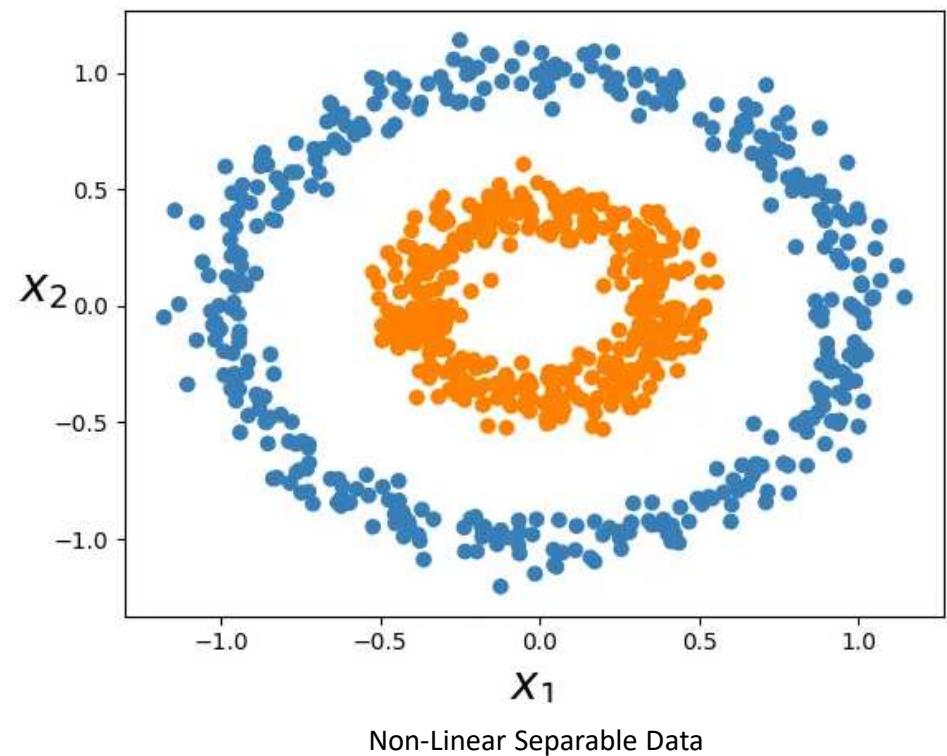

$$y_t (w \cdot x_t + b) \geq 1 \quad \forall t$$

Then the margin is $\frac{1}{||w||}$

or Minimizing $\min_{w,b} \frac{1}{2} ||w||^2$ as per Quadratic Programming

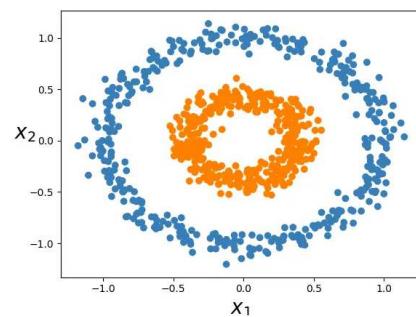

Kernel (Non-Linear) SVMs

- **Kernel Machines** are a class of algorithms for Pattern Analysis
- The methods involve using linear classifiers to solve non-linear problems
- The general task of Pattern Analysis is to find and study general types of relations (eg: Clustering, Correlations, Classifications etc) in datasets

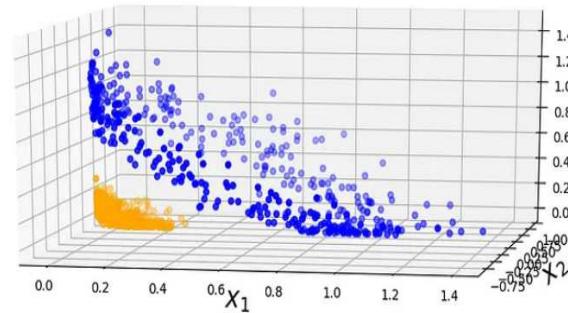

Kernel (Non-Linear) SVMs

- If the data is not linearly separable in the original, or input, space then we apply transformations to the data, which map the data from the original space into a higher dimensional feature space.
- The goal is that after the transformation to the higher dimensional space, the classes are now linearly separable in this higher dimensional feature space.
- We can then fit a decision boundary to separate the classes and make predictions.
- The decision boundary will be a hyperplane in this higher dimensional space.

→

after Data Transformations

Kernel Functions

A function that takes as its inputs vectors in the original space and returns the dot product of the vectors in the feature space is called a *kernel function*

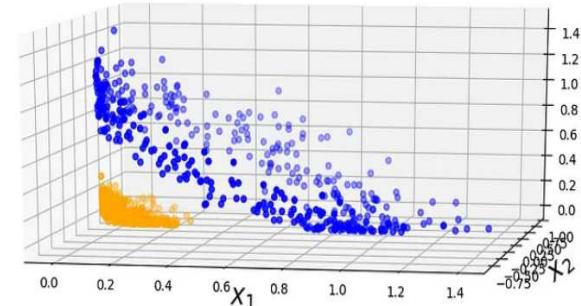

More formally, if we have data $\mathbf{X}, \mathbf{Z} \in X$ and a map $\phi: X \rightarrow \mathbb{R}^N$ then

$$k(\mathbf{x}, \mathbf{z}) = \langle \phi(\mathbf{x}), \phi(\mathbf{z}) \rangle$$

is a kernel function

Kernel Trick: The “Kernel trick” is that the kernel methods represent the data only through a set of pairwise similarity comparisons between the original data observations x

$$\begin{aligned} \phi(\mathbf{a})^T \cdot \phi(\mathbf{b}) &= \begin{pmatrix} a_1^2 \\ \sqrt{2} a_1 a_2 \\ a_2^2 \end{pmatrix}^T \cdot \begin{pmatrix} b_1^2 \\ \sqrt{2} b_1 b_2 \\ b_2^2 \end{pmatrix} = a_1^2 b_1^2 + 2a_1 b_1 a_2 b_2 + a_2^2 b_2^2 \\ &= (a_1 b_1 + a_2 b_2)^2 = \left(\begin{pmatrix} a_1 \\ a_2 \end{pmatrix}^T \cdot \begin{pmatrix} b_1 \\ b_2 \end{pmatrix} \right)^2 = (\mathbf{a}^T \cdot \mathbf{b})^2 \end{aligned}$$

Thank You
